

Nesting success prediction 2005-2025

Prediction of hihi nesting success in Zealandia for five time periods ranging from 2005 to 2025

- These maps predict nesting success (number of fledglings raised per nesting season) around the entire park, for five time periods.
- Prediction was determined using Random Forest, a machine learning method.
- Suitability of areas was calculated based off of recorded nesting success and seven environmental factors: distance to water, feeders, and park border; elevation, slope, aspect, and forest type.
- Each period uses its own Random Forest model.
